What's new? •:.Alterations in T-cell subset distribution in rectal mucosa of patients with ulcerative colitis. The origin, migration, and composition of lymphocytes in the intestine have been the focus of intensive investigation during the past decade. Previous studies have focused mainly on total T cells in colorectal mucosa, despite the existence of significant differences in the population of T cells in various compartments of the intestine. In a previous study, we have shown that the organization of T-cell subsets, ie, CD4+ T cells, CD8+ T cells, and double-negative T cells, is affected in lamina propria of patients with active ulcerative colitis, which may correlate with the pathological changes seen in mucosa. However, the localization of T cells in active ulcerative colitis in the rectal mucosa has not been previously documented. Furthermore, in order to assess the correlation of these differences with the disease process, the pathogenic mechanism, and therapeutic response in ulcerative colitis, mucosal biopsies were obtained from the rectum of patients with active ulcerative colitis, inactive ulcerative colitis, and control patients. Although the distribution and proportion of T cells and T-cell subsets varied in the rectal mucosa of patients with active ulcerative colitis, there was no specific pattern to distinguish this disorder. We found that the distribution of T cells in lamina propria of patients with active and inactive ulcerative colitis is altered from that seen in controls. In this d4474df7b8
